Abstract

Background: Numerous studies have found associations between ambient fine particulate matter (PM_{2.5}) and increased mortality risk. However, little evidence is available on associations between PM_{2.5} and years of life lost (YLL). We aimed to estimate the YLL due to chronic obstructive pulmonary disease (COPD) mortality related to ambient PM_{2.5} exposure.

Methods: A time-series study was conducted based on the data on air pollutants, meteorological conditions and 18,472 registered COPD deaths in Ningbo, China, 2011–2015. The effects of PM_{2.5} on YLL and daily death of COPD were estimated, after controlling long term trend, meteorological index and other confounders.

Results: The impact of PM_{2.5} on YLL due to COPD lasted for 5 days (lag 0–4). Per 10 µg/m³ increase in PM_{2.5} was associated with 0.91 (95%CI: 0.16, 1.66) years increase in YLL. The excess YLL of COPD mortality were 8206 years, and 0.38 day per person in Ningbo from 2011 to 2015. The exposure-response curve of PM_{2.5} and YLL due to COPD showed a non-linear pattern, with relatively steep at low levels and flattened out at higher exposures. Furthermore, the effects were significantly higher in the elderly than those in the younger.

Conclusions: Our findings explored burden of PM_{2.5} on YLL due to COPD and highlight the importance and urgency of ambient PM_{2.5} pollution control and protection of the vulnerable populations.

Keywords: Fine particulate matter (PM_{2.5}), Years of life lost, Chronic obstructive pulmonary disease, Modifications, Exposure-response curve

Background

Ambient fine particulate matter (PM_{2.5}) is one of the most important environmental issues worldwide, and the adverse impact of PM_{2.5} has become a great concern. Many epidemiological studies have provided evidences of associations between PM_{2.5} exposure and excess mortality [1–3]. The majority of these studies had estimated excess mortality using daily death counts as the dependent variable. However, using this indicator might ignore the differences in ages of deaths [4]. From a public health perspective, deaths occurring at different ages are not equally important.

Years of life lost (YLL) is a measure of disease burden that considers the life expectancy at death and, therefore, assigns higher weights to deaths that occur at younger ages [5]. Besides, it is more accurate than mortality to measure premature death and excess mortality [6]. In this sense, exploring the relationships between PM_{2.5} and YLL may provide additional information for policy making and health resource allocation, and has important public health significance.

Chronic obstructive pulmonary disease (COPD), characterized by irreversible airflow obstruction, is a common chronic respiratory disease [7]. Due to the slow progression and chronic nature of the disease, COPD represents a massive and growing disease burden and is an important cause of morbidity and mortality [8]. The Global Burden of Disease study showed that COPD was the third leading cause of deaths in the world and

Full list of author information is available at the end of the article

ranked the ninth of global YLL in 2010 [9]. There is compelling evidence that short-term exposure to particulate matter is a risk factor for the development and exacerbation of COPD [10–13]. However, the availability of studies on the associations between ambient PM_{2.5} and YLL of COPD is rare up to now, and the modifications of socioeconomic factors such as age, gender and marital status are unclear.

With the rapid development in industrialization and urbanization, ambient PM_{2.5} pollution has aggravated in China in recent years. Ningbo, located in the Yangtze River Delta in the southern China, is the world's fourth-largest port city. The population in Ningbo was estimated to be 7.83 million in 2015, distributed in an area of approximately 9816 km². The high level of economic development in the city also caused the ambient PM_{2.5} pollution to be a subject of highly concern.

In this study, we conducted a time-series study to explore the disease burden of COPD from short term ambient PM_{2.5} exposure in Ningbo, China, 2011–2015, using the indicator of YLL.

Methods

Data on mortality and YLL

Daily mortality data on deaths of COPD between January 1st 2011 and December 31th 2015 were obtained from Ningbo Municipal Center for Disease Control and Prevention, and the data was restricted to registered residents only. COPD deaths were identified according to the International Classification of Diseases 10th version (ICD-10: J40–44). The dataset comprised date of death, gender, age and marital status. Daily death count was defined as the number of deaths occurring on a single day.

We calculated YLL by matching the patient's age to the life table for each death. The sex- and age-group specific life expectancy of Chinese population was obtained from the World Health Organization (WHO), and life expectancies for 2011–2015 were averaged (Additional file 1: Table S1). Daily YLL were calculated by summing the YLL for all deaths on the same day. Both daily YLL and deaths counts were stratified by age (<75 and ≥75 years), gender (male and female) and marital status (the married and the widowed).

Exposure assessment

Concentrations of PM_{2.5}, inhalable particulate matter (PM₁₀), sulfur dioxide (SO₂) and nitrogen dioxide (NO₂) were monitored continuously at 11 monitoring sites which cover urban and suburban areas of Ningbo. The concentrations of the air pollutants were measured according to the Chinese National Ambient Air Quality Standard [14]. The Environment Monitoring Center of Ningbo collects the pollutants concentrations from all the monitoring sites of the city and records the hourly

concentrations, from which the daily average levels for all the individual monitoring sites and the whole city levels were derived. Number of missing is less than 1%, and the missing values were substituted with the mean daily value. Daily meteorological data, including temperature and relative humidity, were obtained from the Ningbo Meteorological Bureau.

Statistical analysis

We used generalized additive model (GAM) to explore the impacts of particulate matter on YLL. Because the dependent variable of daily YLL follows a normally distributed (Additional file 1: Figure S1), the family function for GAM was Gaussian.

The model is as follows:

$$YLL_t = \alpha + \sum_{i=1}^q \beta_i(X_i) + \sum_{j=1}^p f_j(C_j, df) + W_t(\text{week})$$

In the model, YLL_t is the observed daily YLL at day t ; α is the intercept; β is the coefficients of YLL associated with per 1 $\mu\text{g}/\text{m}^3$ increase in particulate matter; X_i is the daily mean concentrations of particulate matter; C_j is the confounding factors including time, daily temperature, daily relative humidity; f_j is the smooth functions (natural cubic spline); $W_t(\text{week})$ is the dummy variables for day of week on day t . We applied the penalized spline function of time and 7 degrees of freedom per year was used to control for secular trend and seasonality. Degrees of freedom for temperature and relative humidity were set to 3 according to the previous studies [15, 16]. Considering the lagging effects of temperature, the 14-day moving average of temperature was used. For relative humidity, the average value of the present day was used in the models.

Then, to investigate the lag pattern of PM_{2.5}, potentially delayed and cumulative associations were estimated. We first examined the delayed associations using a single day lag (from lag0 to lag7), as previous studies showed the lag effects of particulate matter were strongest within 7 days [2, 17]. Then the cumulative associations were estimated using the moving average over the lag periods from lag01 (moving average concentrations of day0 and day1) to lag07 (moving average concentrations of day0 to day7). Final results were presented as changes in daily YLL with per 10 $\mu\text{g}/\text{m}^3$ increase in PM_{2.5} in different lag days. Considering the PM_{2.5} effect of 5-day moving average concentrations from day 0 to day 4 (lag04) is strongest, so we use lag04 in our main analysis.

We also calculated the excess YLL as follows:

$$YLL \text{ of COPD advanced by PMt} = \sum_{t=1}^{1826} \text{PMt} \times \beta$$

Where PMt is the concentrations of PM_{2.5} (lag04) in our main studies at day t, β is the value of 1 $\mu\text{g}/\text{m}^3$ particulate matter increase.

Secondly, we used the penalized spline of $PM_{2.5}$ to replace the linear variable of $PM_{2.5}$ to plot the dose-response curve of $PM_{2.5}$ and YLL (Fig. 3). The relationship appeared to be nonlinear and the curve became flattening in high level $PM_{2.5}$ concentration days, so we detected the turning point. The Akaike Information Criterion (AIC) values of GAM models using 1 unit increment in $PM_{2.5}$ within the identified range of threshold were computed between $100 \mu\text{g}/\text{m}^3$ and $150 \mu\text{g}/\text{m}^3$ (Additional file 1: Table S2). The concentration of $PM_{2.5}$ with the lowest AIC value was selected as the turning point. Similar method had been used in previous studies [18–20]. According to the turning point ($128 \mu\text{g}/\text{m}^3$), we created two variables (high concentration level, low concentration level), which were higher or lower than the turning point respectively, to explore the piecewise linear association of $PM_{2.5}$.

In addition, the analyses were stratified by age, gender and marital status. Single pollutant model was used to explore the main association of $PM_{2.5}$ with daily YLL, while two pollutants models with SO_2 or NO_2 added was used to examine the stability of these associations. In order to have a comparison, we also examined the effects of PM_{10} .

Furthermore, we evaluated the impacts of particulate matter on daily death counts of COPD. The independent variable, lag structure and relevant degrees of freedom in the model were similar to those in YLL model, except time series function with the Poisson link under a GAM framework was used because the dependent variable daily death counts following a Poisson distribution. Results were presented as changes in excess risk (ER) of deaths from COPD per $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$ and PM_{10} in different lag days. The equation of ER was as follows:

$$ER = (e^{10 \times \beta} - 1) \times 100\%$$

In the equation, β is the value of daily death counts associated with a unit increase in particulate matter.

An autocorrelation function (ACF) was used in the models to assess whether the residuals were independent over time and the reliability of the models. The results showed no obvious autocorrelations were found (Additional file 1: Figure S2 to Figure S5). Sensitivity analyses were performed on the parameters included in the models to test the robustness of our results. We tested using 4 of degrees of freedom of relative humidity, 4 of degrees of freedom of temperature, and used 6 & 8 of degrees of freedom of time per year in the models.

In this study, the mgcv packages in R software (Version 3.1.2) were used to perform the analyses. $P < 0.05$ (2 side) were considered to be significant. The study was approved by the Institutional Review Board of Ningbo Municipal Center for Disease Control and Prevention (No. IRB 201603).

Results

Mean daily concentrations of $PM_{2.5}$ and PM_{10} were $49.58 \mu\text{g}/\text{m}^3$ and $78.59 \mu\text{g}/\text{m}^3$, respectively during 2011 to 2015 in Ningbo, China (Table 1). Correlations between air pollutants and meteorological conditions were examined by Spearman correlation function and presented in Table 2. Particulate and gaseous pollutant and meteorological conditions were correlated with each other, with the most significant correlations observed between the four air pollutants.

A total of 18,472 registered COPD deaths were identified for the five study years. Daily death counts and YLL of COPD had a mean of 10 and 80 years, respectively. The average daily YLL of the elderly, male and the married ones were higher than that of the young, female and the widowed ones, respectively (Table 1). Both outcomes showed a seasonal trend, with higher values in November through the next April than other months (Fig. 1).

Estimated changes with 95% confidence intervals in YLL due to COPD associated with $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$ in different lag days were presented in Fig. 2. In general, the associations with $PM_{2.5}$ lasted for five days (lag0 to lag4), and gradually reduced after day 4. From day 5 to day 7, the effects had no significance. In addition, the lag patterns were similar for YLL and ER.

The strongest associations were found in 5-day moving average concentrations from day 0 to day 4 (lag04). In single pollutant model, a $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$ was associated with 0.91 (95% CI: 0.16, 1.66) years increase in YLL, and 1.32% (95% CI: 0.52%, 2.12%) increase in ER for COPD deaths, respectively.

We also analyzed the associations of PM_{10} in our study. Per $10 \mu\text{g}/\text{m}^3$ increase in PM_{10} was associated with 0.81 (95% CI: 0.30, 1.33) years increase in YLL and 1.07% (95% CI: 0.51%, 1.63%) increases in ER of COPD death at lag04.

Furthermore, the excess YLL of COPD mortality in Ningbo from 2011 to 2015 were estimated, which were 8206 years. Take the population of Ningbo into consideration, the YLL in days per person of the population for a 365 day period of exposure was nearly 0.38 day per person in Ningbo from 2011 to 2015.

In addition, the exposure-response curve of $PM_{2.5}$ and YLL due to COPD showed a non-linear pattern (Fig. 3). When stratified by the turning point of $PM_{2.5}$, the associations below the turning point concentration were stronger than those above the turning point concentration (Table 3). Specially, the associations of $PM_{2.5}$ -YLL due to COPD was 1.44 (95% CI: 0.57, 2.32) below the turning point concentration, while the value was 0.32 (95% CI: -0.59, 1.23) above the turning point concentration. And the mean age at death for $PM_{2.5}$ concentrations above and below the median are 74.50

Table 1 Daily weather conditions, YLL and death counts of COPD in Ningbo, China, 2011–2015

Variables	Mean ± SD	Minimum	25th	Median	75th	Maximum
PM _{2.5} (µg/m ³)	49.58 ± 32.36	5.86	28.25	41.73	61.25	421.71
PM ₁₀ (µg/m ³)	78.59 ± 48.19	12.86	44.94	66.33	97.97	543.88
SO ₂ (µg/m ³)	21.34 ± 13.84	5.38	12.14	16.94	25.73	112.6
NO ₂ (µg/m ³)	43.41 ± 18.65	7.62	30.12	40.61	55	121.8
Temperature (°C)	17.49 ± 8.94	-1.67	10	18.89	24.44	34.44
Relative humidity (%)	76.41 ± 12.25	31	68	77	86	100
Years of life lost (years)						
Total	80 ± 40	0	51	73	102	278
Age < 75 years	19 ± 20	0	0	13	30	136
Age ≥ 75 years	61 ± 30	0	39	55	77	227
Male	46 ± 27	0	26	42	62	174
Female	34 ± 22	0	17	30	46	161
Married	44 ± 27	0	24	39	59	175
Widowed	33 ± 20	0	18	29	45	144
Daily death counts (No. of deaths)						
Total	10 ± 5	0	7	9	13	34
Age < 75 years	1 ± 1	0	0	1	2	8
Age ≥ 75 years	9 ± 4	0	6	8	11	33
Male	6 ± 3	0	3	5	7	18
Female	5 ± 3	0	3	4	6	20
Married	5 ± 3	0	3	4	7	19
Widowed	5 ± 3	0	3	5	7	20

and 73.87, respectively. Similar pattern were showed for the associations between PM_{2.5} and ER of COPD deaths.

In two pollutants models, the estimates for associations with PM_{2.5} and PM₁₀ did not change much when the gaseous pollutants SO₂ or NO₂ were added in the models. For instance, when SO₂ was added in the model, 10 µg/m³ increasing of PM_{2.5} was significantly associated with 1.28 (95%CI: 0.46, 2.11) person year increase in YLL.

The results of modifications of age, gender and marital status were summarized in Table 4. When stratified by age, the associations were stronger in the elderly (≥75 years)

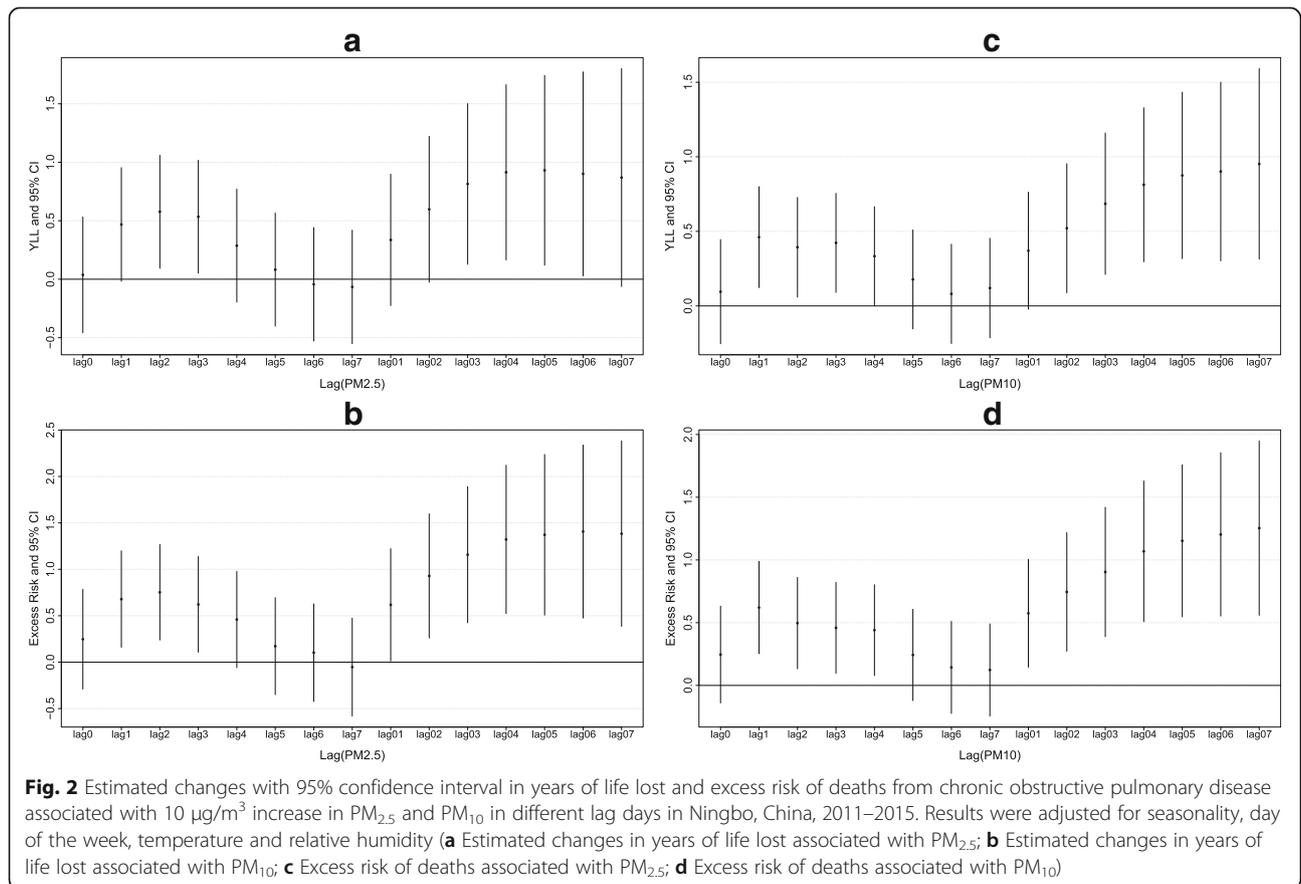

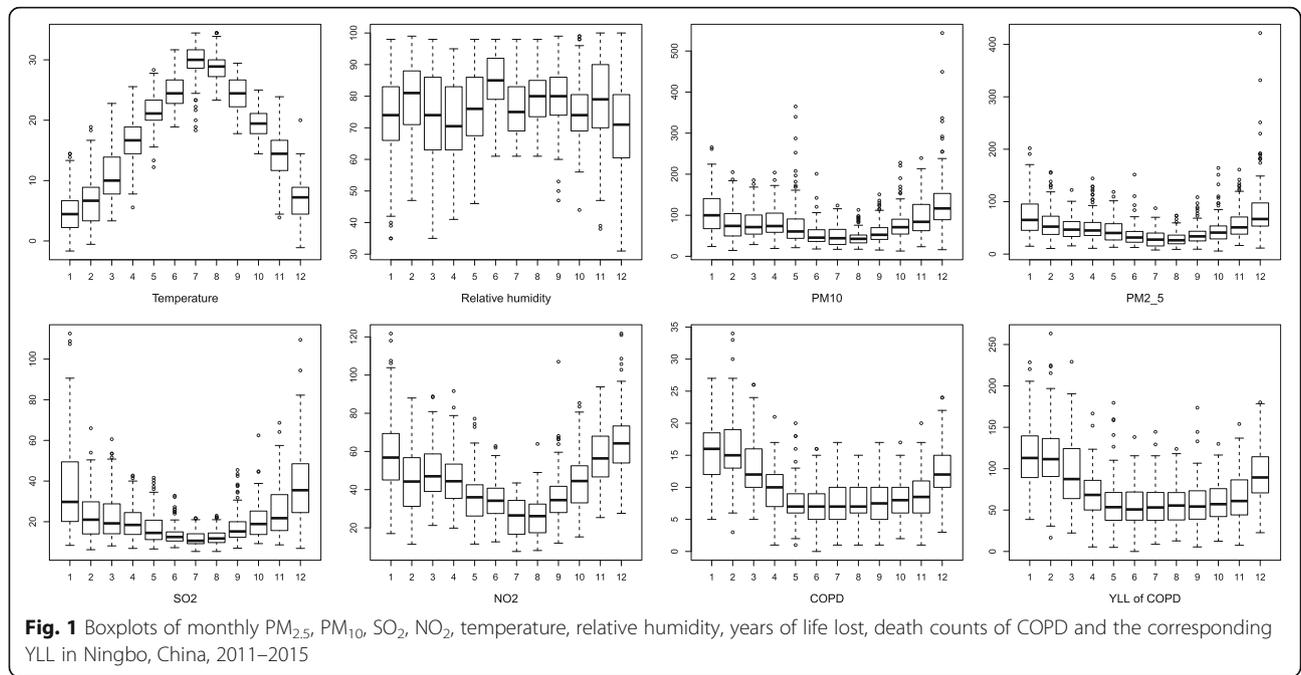

than the younger (<75 years). In the elderly, a 10 µg/m³ increase in PM_{2.5} corresponded to 0.98(95%CI: 0.42, 1.54) years increase in YLL. For the younger, no significant effects were found.

For the modification of gender, the associations between female and male were not significant. For different marital status, the associations in the widowed showed an increased trend compared with the married ones, though the effect estimate of the married was well within the widowed ones..

Sensitivity analyses results showed that the estimations were stable based on the variations of the parameters in the models (Table S4).

Table 2 Spearman correlation between air pollutants and meteorological conditions in Ningbo, China, 2011–2015

	PM _{2.5}	PM ₁₀	SO ₂	NO ₂	Temperature (°C)	Relative humidity (%)
PM _{2.5}	1.00	0.95	0.78	0.76	-0.47	-0.28

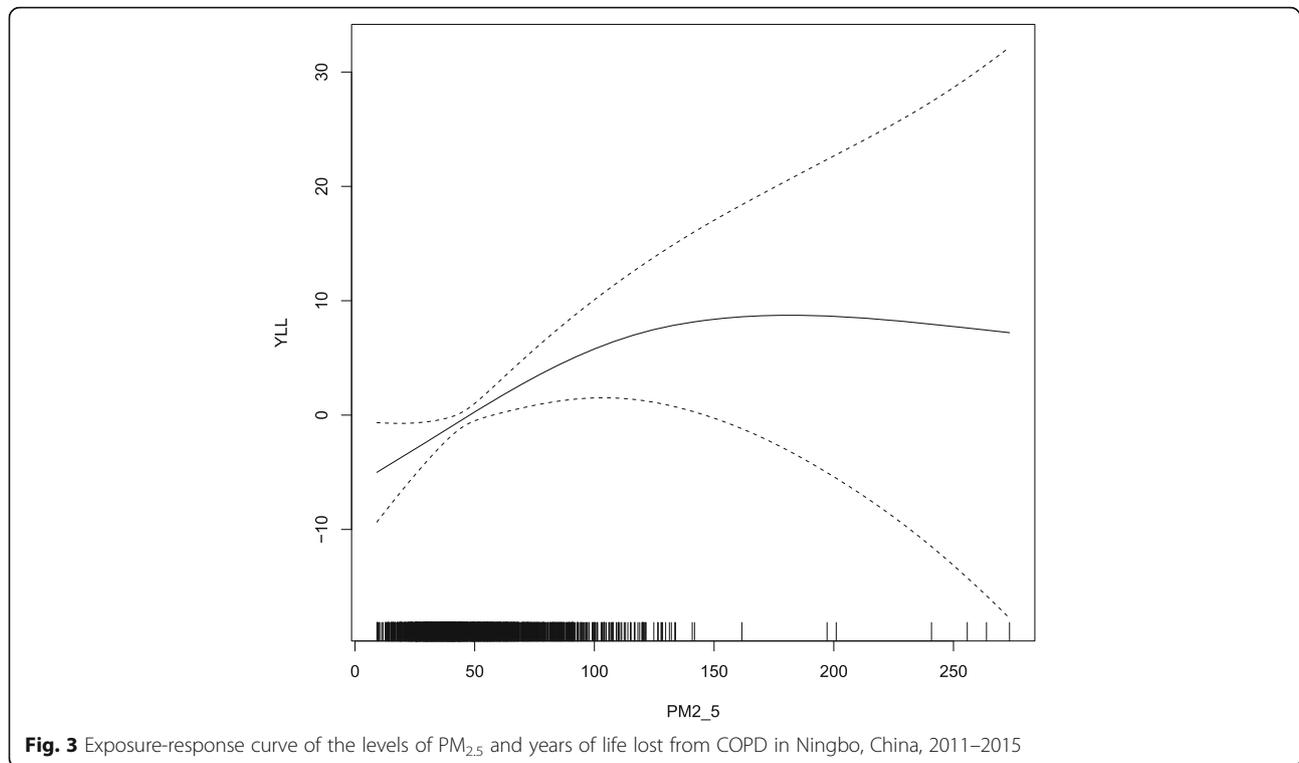

Fig. 3 Exposure-response curve of the levels of $PM_{2.5}$ and years of life lost from COPD in Ningbo, China, 2011–2015

Discussion

The relationships between ambient $PM_{2.5}$ and increased mortality risk were well documented [1–3]. Although previous studies indicated that $PM_{2.5}$ is a significant environment trigger for acute exacerbation of COPD, and thus leading to increasing symptoms, emergency visits, hospital admissions and mortality [10–13]. A study conducted in China showed that 83% of the population lived in areas where $PM_{2.5}$ concentrations exceeded the Chinese Ambient Air Quality Standard of $35 \mu\text{g}/\text{m}^3$, premature mortalities attributed to $PM_{2.5}$ nationwide were 0.17 million for COPD [21]. However, the number of death ignores the difference in ages of deaths, and giving equal weights to the deaths occurring at a young age and those occurring at an old age. From a public health perspective, deaths occurring at different ages are not equally important, dying at a young age results in more potential years of life lost (YLL) [4, 6]. Nevertheless few studies using YLL as dependent variable to explore the health impact of the current exposure levels of $PM_{2.5}$ on COPD deaths in China, possibly due to the lack of individual data needed for calculating YLL.

Our study explored the associations of $PM_{2.5}$ exposure with daily YLL due to COPD for the first time. Based on the data of 18,472 COPD deaths over a five year period in Ningbo, China, we found that $PM_{2.5}$ exposure were significant associated with increased YLL of COPD. Per $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$ was associated with 0.91(95% CI: 0.16, 1.66) years increase in YLL of COPD

deaths. In the study of He 2016 [5], an increase of $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$ was related to 2.97(95%CI: -2.01, 7.95) years of all-cause mortality, which using the data of Ningbo from 2009 to 2013. The comparison showed the impact of $PM_{2.5}$ on YLL from COPD and all-cause mortality is different, although the impact of $PM_{2.5}$ on YLL of all-cause mortality was not significant, there was significant influence on COPD YLL. This indicated more investigations should be carried out to explore the impact of $PM_{2.5}$ on YLL from diseases which are leading cause of death and disease burden such as COPD.

In addition, the excess YLL of COPD mortality was also estimated, which were 8206 years. Take the population in Ningbo into consideration, the YLL in days per person of the population for a 365 day period of exposure was nearly 0.38 day per person from 2011 to 2015, which gives a different perspective from excess death number.

Considering the indicator of YLL is a measure of disease burden that considers the life expectancy at death [6], and has been extensively used to identify and prioritize causes of premature death around the world [22], the results of our study provides a complementary indicator to that of excess deaths, and gives additional information for policy making and health resource allocation.

The exposure-response curve of $PM_{2.5}$ and YLL due to COPD showed a non-linear pattern in Ningbo, 2011–

Table 3 Associations of 10 $\mu\text{g}/\text{m}^3$ increase in $\text{PM}_{2.5}$ and PM_{10} with YLL and ER of deaths from COPD

Pollutants and model	Years of life lost (95% CI)	Percentage increase in death (95% CI)
$\text{PM}_{2.5}$ (Single model)		
Total	0.91(0.16, 1.66)	1.32(0.52,2.12)
Low concentration level	1.44(0.57, 2.32)	1.87(0.91, 2.83)
High concentration level	0.32(-0.59, 1.23)	0.84(-0.10, 1.79)
$\text{PM}_{2.5}$ + SO_2		
Total	1.28(0.46,2.11)	1.61(0.74,2.48)
Low concentration level	1.97(1.00, 2.93)	2.31(1.26, 3.37)
High concentration level	0.65(-0.30, 1.60)	1.12(0.14, 2.11)
$\text{PM}_{2.5}$ + NO_2		
Total	1.07(0.22,1.91)	1.53(0.64,2.42)
Low concentration level	1.45(0.45, 2.44)	1.98(0.97, 3.03)
High concentration level	0.39(-0.59, 1.36)	0.99(-0.05, 1.97)
PM_{10} (Single model)		
Total	0.81(0.30,1.33)	1.07(0.51,1.63)
Low concentration level	1.09(0.52, 1.66)	1.34(0.71,1.98)
High concentration level	0.35(-0.31, 1.01)	0.72(0.03, 1.41)
PM_{10} + SO_2		
Total	1.08(0.51,1.65)	1.28(0.66,1.89)
Low concentration level	1.41(0.79, 2.04)	1.60(0.91, 2.29)
High concentration level	0.59(-0.09, 1.28)	0.91(0.19, 1.63)
PM_{10} + NO_2		
Total	0.96(0.38,1.55)	1.26(0.63,1.89)
Low concentration level	1.18(0.53, 1.83)	1.51(0.82, 2.17)
High concentration level	0.46(-0.25, 1.17)	0.85(1.01, 1.63)

Associations in all concentrations and in low and high concentrations levels were both presented at lag04 (moving average concentrations from day 0 to day4). Single and two pollutants models were used. Data were collected from Ningbo, China, 2011–2015

2015. The curve was relatively steep at low levels and flattened out at higher exposures. Previous studies also found similar pattern under different levels of particulate matter [20, 23, 24]. However, considering there were few observations for $\text{PM}_{2.5}$, cautions should be taken when using the estimations in the high concentration level.

In this study, we found that the associations of $\text{PM}_{2.5}$ on both daily YLL and death counts of COPD were stronger in the elderly (≥ 75 years) than the younger (< 75 years). The difference was plausible from a biological perspective because of the decreased immunologic function and reduced lung function as a natural part of aging, and frailty status which decrease physiologic reserve for

the adverse effects of air pollution, etc. [25, 26]. In addition, elderly individuals frequently have pre-existing chronic diseases, which may make them more vulnerable to the adverse influence of particulate matter exposure [27, 28]. The higher impact in the elderly was consistent with a previous study conducted in Ningbo which explored the air pollution-YLL relationships [5], while was different from the results from Beijing which indicated the influence of particulate matter on daily YLL was higher in the younger people [4]. Considering the annual concentrations of $\text{PM}_{2.5}$ and PM_{10} were 105.1 $\mu\text{g}/\text{m}^3$ and 144.6 $\mu\text{g}/\text{m}^3$ in the Beijing study, the difference may be due to the different levels of particulate matter in Beijing and

Table 4 Associations of $\text{PM}_{2.5}$ with YLL and ER of COPD deaths stratified by age, gender and marital status

Indicator	Age		Gender		Marital status	
	< 75 years	≥ 75 years	Male	Female	Married	Widowed
Years of life lost (95% CI)	-0.06 (-0.54,0.42)	0.98 (0.42,1.54)*	0.47 (-0.08,1.01)	0.45 (-0.04,0.94)	0.27 (-0.30,0.84)	0.63 (0.21,1.05)
Percentage increase in death (95% CI)	-0.05 (-2.39,2.30)	1.49 (0.65,2.33)*	1.12 (0.06,2.18)	1.57 (0.39,2.74)	0.84 (-0.31,2.00)	1.76 (0.66,2.86)

Associations were presented at lag04 (moving average concentrations from day 0 to day4) with 10 $\mu\text{g}/\text{m}^3$ increase in $\text{PM}_{2.5}$. Data were collected from Ningbo, China, 2011–2015. * $P < 0.05$

Ningbo, which implied the associations of particulate matter and YLL would be different in various pollution levels.

For gender modification, although previous study indicated that female may be more susceptible to particulate matter pollution because female is a risk factor for developing airflow limitation and consequently COPD [29], furthermore, female with COPD would have worse prognosis due to more pronounced dyspnea, lower BMI, and more frequent anxiety [30], we did not found significant differences between gender.

It's the first time to explore the potential effect modification of marital status in the particulate matter exposure and YLL relationships, though non significance was found. Further investigations still need to be carried out in future.

In our study, we also evaluated the particulate matter exposure and ER of death counts in our study. Our results showed a 10 $\mu\text{g}/\text{m}^3$ increase in $\text{PM}_{2.5}$ and PM_{10} were associated with maximum increases in ER of death counts of 1.32% (95%CI: 0.52%, 2.12%) and 1.07% (95%CI: 0.51%, 1.63%) at lag04, respectively. The results were supported by previous studies. For instance, meta-analysis of 31 studies showed that a 10 $\mu\text{g}/\text{m}^3$ increase in PM_{10} was associated with increase in COPD mortality with an OR of 1.011 (95%CI: 1.008, 1.014) [31]. A study conducted in Guangzhou also found an increase of 10 $\mu\text{g}/\text{m}^3$ increase in PM_{10} was associated with 1.58% (95%CI: 0.12%, 3.06%) increase of COPD mortality [19].

This study has several strengths. First, our study explored the associations between $\text{PM}_{2.5}$ exposure and YLL due to COPD for the first time, and the excess YLL were also calculated. Using YLL as a key indicator to measure the impact of particulate matter on premature deaths will provide more information for policy making and resources allocation. Secondly, exploring the exposure-response curve of $\text{PM}_{2.5}$ on YLL due to COPD was the first time. We found the exposure-response curve was nonlinear and the associations were steeper in the low $\text{PM}_{2.5}$ concentrations and became flattening in the high $\text{PM}_{2.5}$ concentrations. Thirdly, the modification of socioeconomic factors especially the marital status was first investigated, and provided complementary information for identifying vulnerable subgroups.

However, the data used in the study were only from one city, and cautions should be taken when generalizing the results to other geographic areas. In addition, we used ambient particulate matter from fixed site rather than individual exposure, which may result in measurement error, and the individual risk factors such as smoking, drinking and underlying diseases were unknown and not controlled in the study. Furthermore, as we used time series method to estimate the effects which was considered inappropriate to estimate long-term effects [32], it should be careful when analysing the long-term associations.

Conclusions

In conclusion, our study provided a new insight into the disease burden due to COPD of ambient $\text{PM}_{2.5}$ exposure. We found that $\text{PM}_{2.5}$ had significant impacts on YLL due to COPD in Ningbo, China. Furthermore, the exposure-response curve was nonlinear and the associations were steeper at low levels and became flattened out at higher exposures. The elderly were susceptible population. Our findings highlight the importance and urgency of ambient $\text{PM}_{2.5}$ control and protection of the vulnerable populations.

Acknowledgements

We thank the Ningbo Municipal Center for Disease Control and Prevention and the Environment Monitoring Center of Ningbo for providing the health data and air pollution data, respectively. Moreover, we thank the Ningbo Meteorological Bureau for providing the meteorological data.

Funding

This work was supported by the National Natural Science Foundation of China (No. 81372950 and No. 81502780), the National Key Research and Development Program of China (No. 2016YFC0207103 & No. 2016YFC0206506), Young Elite Scientists Sponsorship Program by the China Association for Science and Technology (No.2016QNRC001), the Medical Technology Program Foundation of Zhejiang, China (2014KYA202) and Science and Technology Program of Ningbo, China (No.2014C50027). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Availability of data and materials

Raw data of COPD mortality and daily air pollution concentrations were requested and obtained from Ningbo Municipal Center for Disease Control and Prevention and the Environment Monitoring Center of Ningbo, respectively. The raw meteorological data were obtained from the Ningbo Meteorological Bureau. Raw data will not be shared because the authors are not authorized for distribution of data.

Authors' contributions

GL and JH designed the study and developed the analysis plan. GL performed statistical analyses and took responsibility for the accuracy of the data analysis. JH wrote the manuscript. These two authors contributed equally to the study. GX gave suggestions for the implementation. XP gave advice for the statistical analysis. XQ collected the data. JX and TZ took responsibility for the integrity of the data. YZ conducted the literature review and QL helped prepare and

method section. XG gave advice for the designation of the study. TH directed its implementation, reviewed and edited the manuscript. All authors contributed to the revision and approved the final manuscript.

Competing interests

The authors declare that they have no competing interests.

Consent for publication

Not applicable.

Ethics approval and consent to participate

The study was approved by the Institutional Review Board of Ningbo Municipal Center for Disease Control and Prevention (IRB 201603). Informed consent was not required because the data used in the study were deaths registration records and the data were anonymous.
